Quarterly Report: Q4 FY01

LLNL Input

A model of the 28-inch, laboratory mill at Alcoa Technical Center was constructed, and a preliminary calculation run using an estimated initial ingot size and pass schedule to assess the computational requirements for the simulations and to develop a procedure for adjusting the mill configuration and model boundary conditions between passes. The simulation was run through three passes, and the mechanical and contact thermal boundary conditions appear to be working appropriately. The figure shown below is a contour plot of the thermal field after three passes.

A summer student at LLNL studied the effects of the spatial discretization on the accuracy of the thermal contact solution. The results of this work provide a guide for selecting the proper element size to give a desired level of accuracy for the thermal solution. The mesh in the figure below is too coarse to guarantee that the transient temperature field is accurate to within 10 degrees. Additional mesh refinement is needed. In anticipation of this, it was confirmed that this calculation would run effectively in parallel on the Compaq cluster at LLNL.

This work was performed under the auspices of the U.S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under Contract No. W-7405-Eng-48.

The actual ingot geometry and pass schedule were received from Alcoa late in the quarter and the geometry has been modified to account for the correct ingot size. Some aspects of the thermal treatment need further development. These include accounting for the inter-pass delay on heat conduction within the roll and incorporating film coefficient boundary conditions consistent with natural convection to the air and the coolant/lubricant sprayed on the roll. Appropriate film coefficients will be obtained from Alcoa.

Alcoa Input

- Determine material constitutive properties (Alcoa proprietary data):
The constitutive property of an aluminum alloy from 5xxx series has been obtained by using the hot tensile testing fixture conducted at the Deformation Simulator at Alcoa Technical Center.

The constitutive equation of this alloy was formatted in a hyperbolic sine type equation in terms of temperature, strain rate, and flow stress. Four material constants were determined.

- Characterize hot rolling process: boundary and initial conditions (protected CRADA information)

The boundary and initial conditions of hot rolling process were quantified from experiments conducted at the 28" hot mill at Alcoa Technical Center. These conditions would include roll geometry, roll speed, initial roll temperature, slab geometry, and initial slab temperature. A rolling schedule of the alloy mentioned above was established for rolling experiments and for numerical simulation purpose.

Note:

1. Alcoa proprietary data means the data was developed by Alcoa before this CRADA activity started
2. Protected CRADA information means Alcoa data was produced in performance of this CRADA project. This data can not be released for 5 years
3. All data generated by LLNL under this CRADA project is restricted under the rules governed by "Protected CRADA Data"
